

PROBLEM STATEMENT

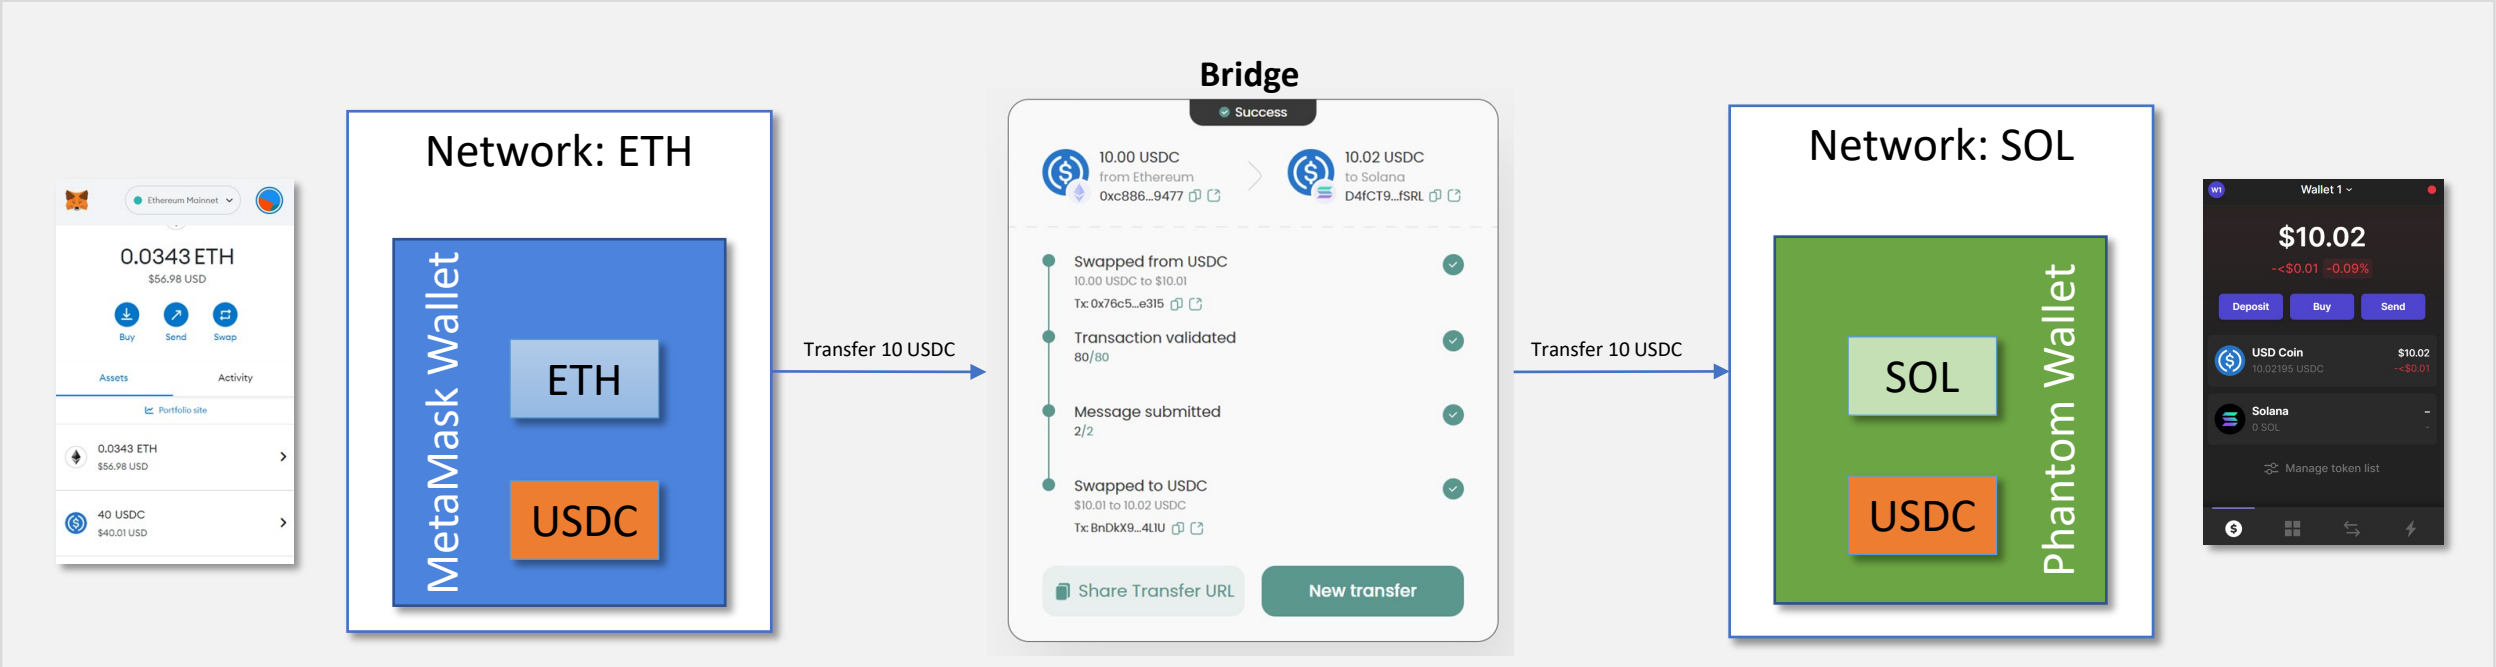

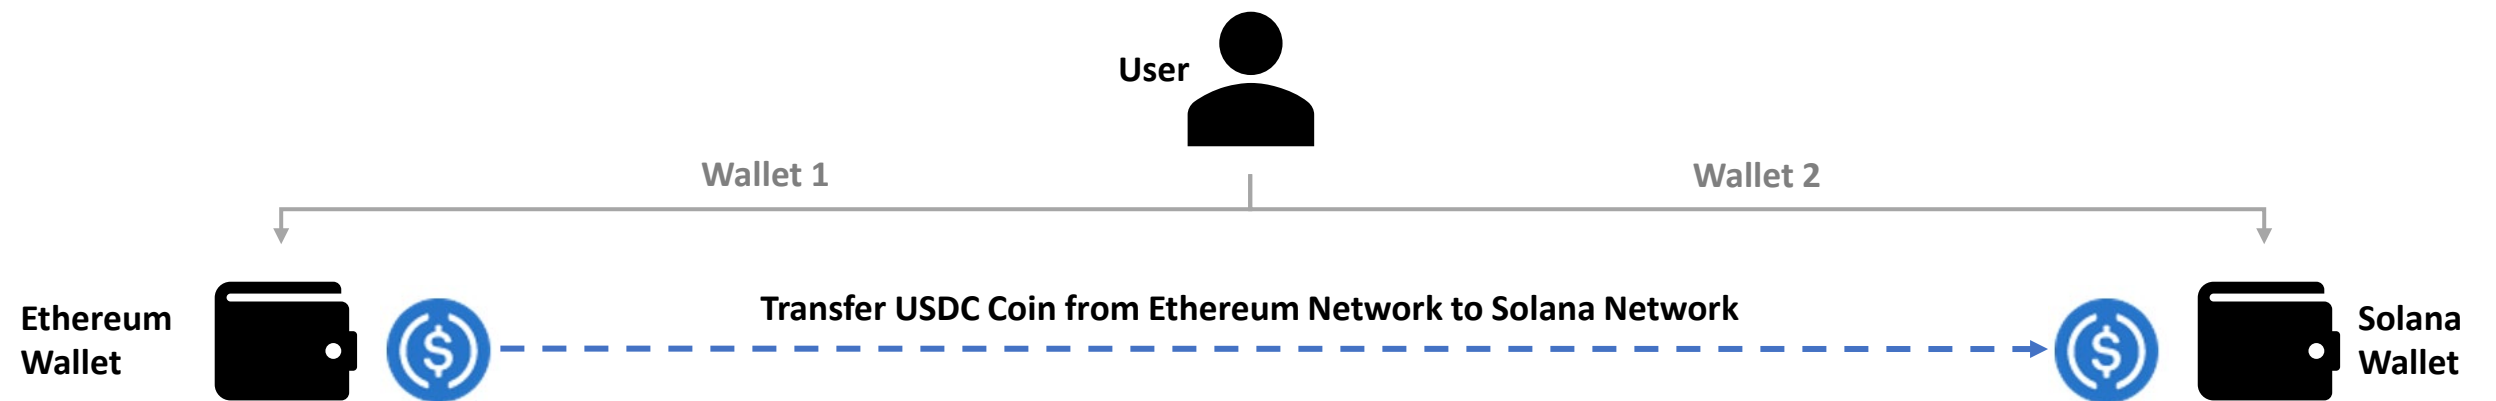

Sophisticated investors who transfer tokens between multiple chains have a difficult time identifying and reporting those transactions to the tax authority at the end of the year among hundreds of other transactions.

SOLUTION

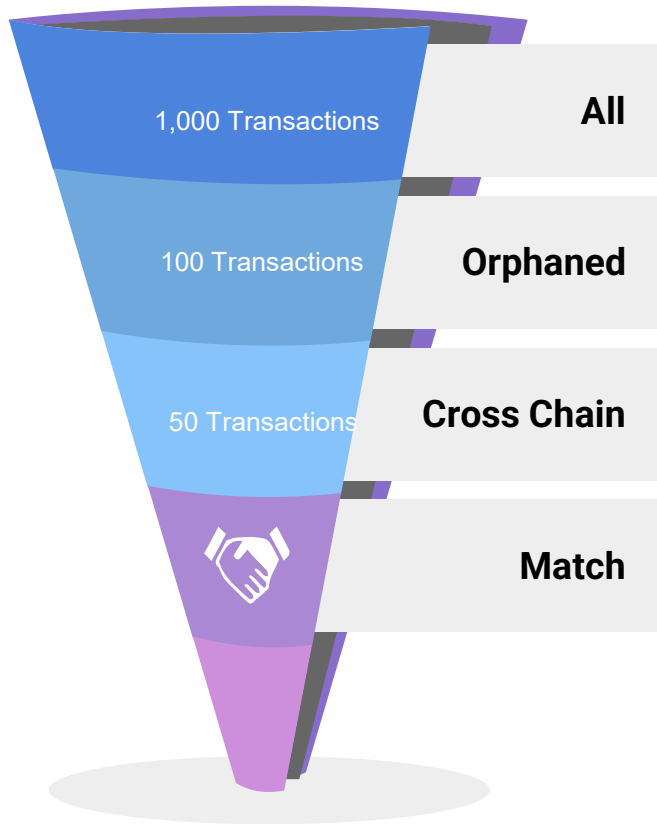

Picks orphan transactions from the user's portfolio and matches an inbound transaction to each outbound transaction.

This helps the user to settle transactions as a transfer between two chains rather than a withdrawal and a deposit.

SCENARIO

Cross-Chain Transaction Matching Algorithm

The total number of transactions in the user portfolio for the last 12 months.

In certain circumstances, users may be unable to locate their deposit/withdraw or cross-chain transactions between wallets, which are listed as orphaned transactions.

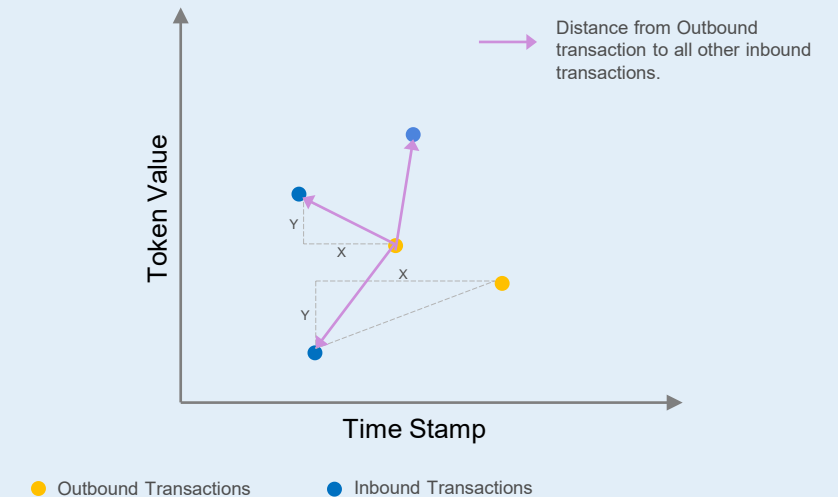

Our algorithm identifies & filters possible cross-chain transactions.

Map any incoming transactions with potential outbound cross-chain transactions.

Euclidean Distance

Euclidean distance is a mathematical concept that measures the length of a line segment between two points in Euclidean space.

We are leveraging Euclidean distance for the matching function to find the closest matching transactions.

Next Steps

To improve the efficacy of our portfolio management solution, we are planning to integrate the Cross-Chain Transaction Matching Algorithm.
